

How to create a blob container in a Storage Account who has a virtual network integration configured?

MN

Problem: You have created a storage account compliant to our company rules who are enforced by policies. The internet access is disabled of the storage account (otherwise you cannot create one), therefore you cannot create a blob container in this storage account as long as you have not integrated the storage account with the virtual network or a private endpoint (not in scope in this blog). This integration means, that you have to access the storage account from inside of virtual network where it is integrated.

Solution: The resource from where you want to create your blob container in the storage account must be inside of the same virtual network. Therefore the gitlab runner or the virtual machine from where you want to configure the blob container must reside in the virtual network where the storage account is integrated.

The picture below shows the setting. After the creation of the storage account you would like to create the blob container. In step **1** you are doing the virtual network integration and in the subnet you have chosen a service endpoint is created. Afterwards you can create in step **2** from the virtual machine inside of the virtual network the blob container and access them also from there. Note, the nsg-defaultnetworking network security group must allow the access to the subnet with the storage endpoint from the virtual machine or you have the storage endpoint in the same subnet as the virtual machine. DNS resolution ist transparent and no action is needed.
